### ABSTRACT

A new fluorimetric and colorimetric dual-mode probe, 4-bromo-2-(hydrazonomethyl) phenol (**BHP**) has been synthesized and successfully utilized for the recognition of Cd<sup>2+</sup>/F<sup>-</sup> ions in DMSO/H<sub>2</sub>O (9:1, v/v) system. The probe displays dual channel of detection via fluorescence enhancement and colorimetric changes upon binding with F<sup>-</sup> and Cd<sup>2+</sup> ions respectively. The Job's plot analysis, ESI-MS studies, Density Functional Theoretical (DFT) calculations, <sup>1</sup>H NMR and <sup>19</sup>F NMR titration results were confirmed and highly supported the 1:1 binding stoichiometry of the probe was complexed with Cd<sup>2+</sup>/F<sup>-</sup> ions. Furthermore, intracellular detection of F<sup>-</sup> ions in HeLa cells and fluorescence imaging analysis in Zebrafish embryos results of the probe **BHP** might be used to reveal their potential applications in a biological living system.

## 1. Determination of Binding constant from Benesi-Hildebrand method

The binding constant of Cd<sup>2+</sup>/F<sup>-</sup> with **BHP** has been calculated by using UV-visible and Fluorescence spectrometer respectively. The fixed concentration of **BHP** was used throughout the titration and any given concentration of F<sup>-</sup> with **BHP** gives good linear relationship. The binding constant value of F<sup>-</sup> with **BHP** was determined by using Benesi-Hildebrand eqn<sup>1</sup>.

$$1/(A-A_0) = 1/\{K(A_{max}-A_0)[F^-]\} + 1/[A_{max}-A_0]$$

Here, A<sub>0</sub> is the absorbance of **BHP** without F<sup>-</sup> ions, A is the absorbance of **BHP** with F<sup>-</sup> ions (at given concentration), A<sub>max</sub> is the absorbance of **BHP** with F<sup>-</sup> ions (in saturated concentration). K is the association constant (M<sup>-1</sup>). The association constant (K) could be determined from the slope of plot 1/(A-A<sub>0</sub>) vs 1/[F<sup>-</sup>].

Further, the binding constant values of F<sup>-</sup> with **BHP** have been calculated by using a fluorescence method. The concentration of **BHP** was kept constant throughout the titration and varying the concentration of the F<sup>-</sup> gives good linear relationship. The binding constant value of F<sup>-</sup> with **BHP** was calculated from by using modified Benesi - Hildebrand equation<sup>2</sup>.

$$1/I-I_{min} = 1/I_{max}-I_{min} + (1/K[C]) (1/I_{max}-I_{min})$$

Here, I<sub>min</sub> is the emission intensity of **BHP** without F<sup>-</sup>, I is the emission intensity of **BHP** with any given concentration of F<sup>-</sup>, I<sub>max</sub> is the emission intensity of **BHP** at a concentration of complete saturation, K is the binding constant, [C] is the concentration of **BHP**. The value of K has been determined from the slope of the plot (I<sub>max</sub>-I<sub>min</sub>) / (I-I<sub>min</sub>) vs 1/[C] for **BHP**- F<sup>-</sup>.

## 2. Determination of Limit of Detection (LOD)

The limit of detection was calculated using this equation<sup>3</sup>.

$$DL = CL \times CT$$

where **CL** is the Conc. of Ligand, **CT** is the Conc. of Titrant at which changes are observed.

The LOD values of F<sup>-</sup> ions;  $DL = 5 \times 10^{-6} \text{ M} \times 0.1 \times 10^{-5} \text{ M} = 0.05 \text{ nM}$ .
